

# AI Engineer Skills Assessment Exercise - Briefing Note

May 2026

## Background

WISDOM INVESTING makes long term equity investments in high-conviction stocks for 1-20 years to benefit from long-term compounding. Over the years, it has accumulated a rich database of transactions made in the markets. This history of sale and purchase decisions reflect the investment & capital creation philosophy of the firm.

## Supporting Data and Information

- 10-year trade data for 4 scripts in WISDOM's portfolio, spanning 2015-25
- Latest analyst research reports for the 4 scripts
- Financial results, annual reports, earnings calls and investor presentations – can be sourced from company websites (investor relations page)
- WISDOM's investment principles, documented
- Other useful reference sites:
  - Screener.in (company financials and documents at one place)
  - Yahoo Finance (historical market prices)
  - NSE and BSE

## Goal of Exercise

The goal is to create an intelligent portfolio management system for WISDOM. For this exercise, assume the portfolio contains 4 scripts only

Step 1: Use the historical trade data provided to *generate insights* on the investor's investment style drawing out strengths and biases. You may score investor behaviour based on timing and sizing decisions for these scripts/portfolio

Step 2: Build an *Intelligent Portfolio Manager* (prototype) that is based on WISDOM's investment principles, insights from historical trade analysis, analyst reports and company fundamentals. It should enable decision making for the investor (buy/sell/hold decisions over time) to exceed their investment goals assuming a universe of these 4 stocks. You are free to use any system architecture of choice (e.g., RAG based, quant based, etc.). Also state any assumptions that you make, e.g., corpus available, frequency of decision making, thresholds for financial metrics etc.

Step 3: Describe *foundational architecture decisions* pertaining to

**Data pipelines** - how trade data, market data, and research/filings are ingested, refreshed, and made query-ready.

**Data security & privacy** - how proprietary trade history and any client data are protected at rest, in transit, and in LLM calls.

**LLM usage** - where the LLM sits in the system, what it's used for vs. not, and how you handle accuracy/hallucination risk in a financial context.

**AI agents (if used)** - whether the system relies on autonomous or multi-step agents, what they're responsible for, and how you handle reliability, guardrails, and human-in-the-loop oversight for financial decisions.

**Cloud** - deployment model and the one or two services you'd anchor on, with why.

Step 4: Export and share your AI coding session history from whatever tool you used (e.g. Claude Code, Cursor, Windsurf, Copilot). This isn't graded on polish - we want to understand how you actually work with AI coding tools: how you break down problems, prompt, course-correct when the model goes wrong, and decide what to accept vs. rewrite yourself.

## Notes

- All data shared is proprietary and should be used for the purpose of prototype development only; files downloaded should be deleted post the assessment
- Use development environment and LLM of your choice
- Share results and supporting links to [aryaman@enam.com](mailto:aryaman@enam.com) within 24 hours of issue of the assessment material including,
  - A writeup
  - GitHub repository, for code written
  - A short 5-min audio/ video recording that explains how the system works
